Slime – An overview

Some initial remarks

- Outline

Slime – An overview

- **Some initial remarks**

- Development

- Related stuff

- `.emacs` bits

Slime – How does it work?

Slime – What can it do?

- > 5 years old
- > 42k loc
- > 1600 ChangeLog entries
- > 100 contributors
 - Code base sometimes feels like a gigantic, mutually shared `.emacs`
 - or IOW, a big ball of mud:
 - no code poetry, but in general quite readable.

Use the source, Luke!

Development

- Outline

Slime – An overview

- Some initial remarks
- **Development**
- Related stuff
- .emacs bits

Slime – How does it work?

Slime – What can it do?

- No release management
 - You're supposed to check out (and update) from CVS.
 - SLIME is mostly hacked during semester breaks, so it's safe to update in Nov/Dez and Jul/Jun.
 - Website terribly out of date.
 - Likewise last official release, Slime-2.0, has a veery long beard.
- Changes are not necessarily backwards-compatible!
- But if something bugs you, or you miss something, drop a mail to `slime-devel@common-lisp.net`.

Related stuff

- Outline

Slime – An overview

- Some initial remarks
- Development
- **Related stuff**
- .emacs bits

Slime – How does it work?

Slime – What can it do?

Stuff to use in combination with SLIME:

- Taylor Campbell's *paredit*
(<http://mumble.net/~campbell/emacs/paredit.el>)
- Michael Weber's *redshank*
(<http://www.foldr.org/~michaelw/emacs/redshank/>)

“Alternatives” to SLIME:

- Symbolics Lisp Machine (<http://www.symbolics.com>)
- *Cusp* for Eclipse (<http://www.bitfauna.com/projects/cusp/>)
- *Limp* for Vim (<http://common-lisp.net/project/limp/>)

.emacs bits

- Outline

- **.emacs bits**

- Slime – How does it work?

- Slime – What can it do?

```
;;; A basic slime configuration (2008-12-03)

(add-to-list 'load-path "/home/tcr/.emacs.d/slime/")
(add-to-list 'load-path "/home/tcr/.emacs.d/slime/contrib/")

(require 'slime)

;; Important(!): 'slime-fancy' is the meta contrib that will enable
;;               all sorts of advanced features.
(slime-setup '(slime-fancy slime-asdf))

;; ("foo") means that the programm "foo" is tried to be executed.
(setq slime-lisp-implementations
      '((acl70      ("mlisp")      :coding-system utf-8-unix)
        (clisp      ("clisp")      :coding-system utf-8-unix)
        (cmucl      ("lisp")       :coding-system iso-latin-1-unix) ; unicode available soon!
        (sbcl       ("sbcl")       :coding-system utf-8-unix)
        (sbcl-git   ("sbcl-git")   :coding-system utf-8-unix)
        (sbcl-cvs-no-utf8 ("sbcl-cvs"))))

;; 'M-x slime' will execute this entry in 'slime-lisp-implementations'.
;; You can specify another entry to be used by 'M-- M-x slime'.
(setf slime-default-lisp 'sbcl-git)
```

- Outline

Slime – An overview

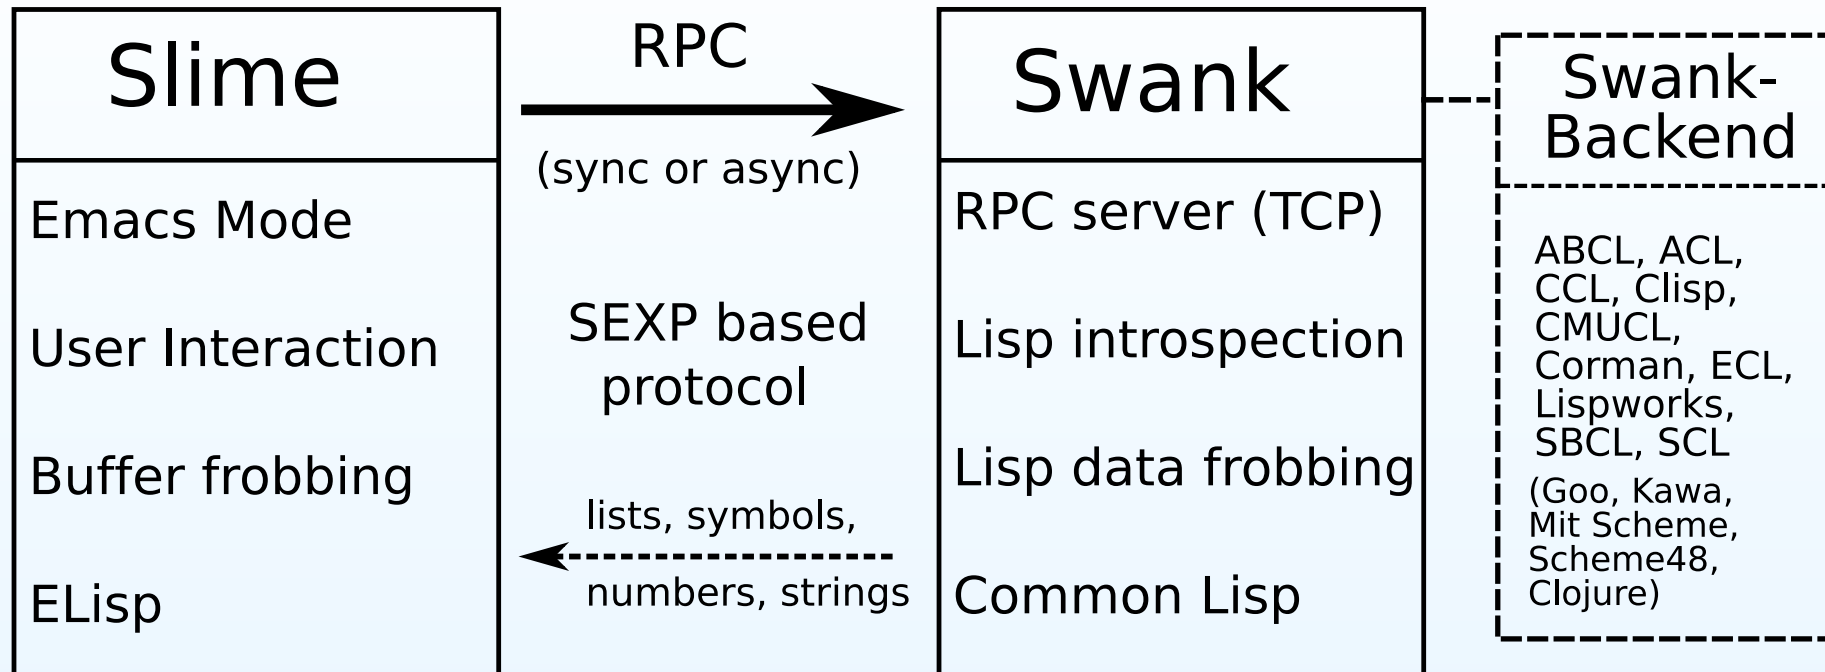

Slime – How does it work?

- Architecture
- Implementation bits
- More implementation bits
- RPC protocol
- An example: C-c C-m

Slime – What can it do?

Slime – How does it work?

Architecture

- Remote (and reattachable!) sessions possible (securing e.g. via ssh tunneling)
- Multiple simultaneous connections to different implementations possible

Implementation bits

- Outline

Slime – An overview

Slime – How does it work?

- Architecture
- **Implementation bits**
- More implementation bits
- RPC protocol
- An example: C-c C-m

Slime – What can it do?

The Swank server is implemented differently depending on what the backend supports. On some implementations, you can even choose which characteristics you want—by tweaking the variable `*COMMUNICATION-STYLE*`:

- `:spawn`

Using different threads:

- reader thread (polling)
- control thread (dispatching)
- repl thread (executing repl requests)
- worker threads (executing misc user requests)

- `:fd-handler`

Using `SERVE-EVENT`: A `select()`-based polling framework to asynchronously invoke callbacks when a polled FD becomes available.

- `:sigio`

Using POSIX signals (`SIGIO`.)

- `nil`

Busy waiting.

More implementation bits

- Outline

Slime – An overview

Slime – How does it work?

- Architecture
- Implementation bits
- **More implementation bits**
- RPC protocol
- An example: C-c C-m

Slime – What can it do?

When browsing `swank.lisp`, watch out for

- DEFSLIMEFUN
Defines a function that can be invoked via an RPC from SLIME:
 - receives data from Emacs, returns data to Emacs (caution: no real automatic marshalling.)
 - function's name automatically exported from SWANK package.

The file `swank-backend.lisp` defines lots of function prototypes that are supposed to be implemented by the actual backends in `swank-<foo>.lisp`

- DEFINTERFACE
Defines such a function prototype; a default implementation can be given.
- DEFIMPLEMENTATION
Defines an actual implementation for a function prototype; overwrites default implementation.

A warning for unimplemented prototypes is signalled during startup.

RPC protocol

- Outline

Slime – An overview

Slime – How does it work?

- Architecture
- Implementation bits
- More implementation bits
- **RPC protocol**
- An example: C-c C-m

Slime – What can it do?

Packet encoding:

- packet header = length, packet payload = sexp
- sexp format shared between Elisp and Common Lisp:
 - lists
 - symbols (explicitly qualified, except for T, NIL, and QUOTE)
 - numbers (fixnums, single-floats)
 - strings (encoding settings must be isomorphic)

Protocol semantics:

- based on so-called events (lists + keyword as CAR):
 - `(:emacs-rex form package thread-id cont-id)`
 - `(:return value cont-id)`
 - `(:emacs-interrupted thread-id)`
 - `(:indentation-update symbol-table)`
 - `(:presentation-start pres-id &optional target)`
 - `(:presentation-end pres-id &optional target)`
 - ...

An example: C-c C-m

- Outline

Slime – An overview

Slime – How does it work?

- Architecture
- Implementation bits
- More implementation bits
- RPC protocol
- An example: C-c C-m

Slime – What can it do?

Emacs side

- C-c C-m is `slime-macroexpand-1`:
- grabs string representation of form at point from the buffer
- invokes RPC `swank:swank-macroexpand-1` via `slime-eval-async`
- sends `(:emacs-rex (swank:swank-macroexpand-1 “(foo ...)”))`
over the wire

...

An example: C-c C-m

- Outline

Slime – An overview

Slime – How does it work?

- Architecture
- Implementation bits
- More implementation bits
- RPC protocol
- An example: C-c C-m

Slime – What can it do?

Swank side

- Reader Thread polls on socket...
- receives packet with `(:emacs-rex ...)`, passes it to Control Thread
- Control Thread dispatches on payload `(:emacs-rex ...)`:
- spawns Worker Thread to execute
`(eval-for-emacs '(swank:swank-macroexpand-1 "(foo ...)"))`
- evaluates `(swank:swank-macroexpand-1 "(foo ...)")`:
- READS the `"(foo ...)"`, calls `MACROEXPAND` on it
- result passed to Control Thread, which sends
`(:return "...expansion...")` back over the wire
- ...

An example: C-c C-m

- Outline

Slime – An overview

Slime – How does it work?

- Architecture
- Implementation bits
- More implementation bits
- RPC protocol
- An example: C-c C-m

Slime – What can it do?

Emacs side again

- when Emacs goes idle, available input from the inferior Lisp is processed
- dispatches on payload (`:return ...`)
- invokes continuation with received value “`(...expansion...)`” (the continuation was stored by `slime-eval-async` previously.)
- continuation pops up buffer, inserts the expansion, indents and finally fontifies it.

- This talk is based on SLIME checked out on 2008-12-11, and SBCL 1.0.22.
- Make sure that you use the `slime-fancy`, and `slime-asdf` contrib.
- The talk will not be about `sexp` frobbing. For that, let me refer you to `paredit`'s documentation.

All Slime operations are performed within global *or buffer-local* context:

- current connection

buffer-local, for example, in Macroexpansion buffers—so further in-place macroexpand operations (see later) are performed within the original connection.

- current thread

buffer-local for SLDB buffers, as you can interrupt specific threads.

- current package

in `.lisp` buffers, the buffer's current package is determined by searching backwards for “(in-package ...)” forms.

- &c

Modeline indicates the context as follows:

- Slime[swank, sbcl{n}]
Connected to “sbcl” with “swank” being buffer package and “n” pending (non-debugged) requests.
- Slime[swank, CON:sbcl{n,m}]
Like above, but there are additional “m” debugged requests.
- Slime[sbcl]
No buffer package could be determined, so *PACKAGE* is implicitly used. Furthermore, there are no pending requests.
- Slime[swank, sbcl{local}]
The connection is buffer local; changing the default connection won't affect operations in this buffer.
- Slime[swank, {stale}]
A local connection was closed; this buffer thus became useless.

Compilation & Evaluation

- &c

Compilation

- C-c C-c, compile & load defun at point
- C-u C-c C-c, like above but compiled with maximum debug settings
- C-c C-k, compile & load buffer
- C-c M-k, compile only buffer¹
- M-x slime-compile-region, compile & load region²

Evaluation

- C-M-x, evaluate defun at point (**reevaluates** DEFVAR forms!)

¹Useful for solely testing compile-time effects.

²Useful for block-compiling regions involving EVAL-WHEN forms, or inlined functions.

Compilation & Evaluation

Compilation Notes

- in `*SLIME Compiler-Notes*` buffer
 - RET, jump to offending source location
- in `.lisp` buffer
 - M-n, go to next note overlay
 - M-p, go to previous note overlay
 - C-c M-c, delete all note overlays from the buffer

Arglist Display

- Outline

- Arglist display for functions, methods, macros, special-forms.
 - `type “(remove ”`
 - `type “(unwind-protect ”`
- Arglist display for declare expressions and type specifiers
 - `type “(declare (inline ”`
 - `type “(declare (type (simple-array ”`
- Contextual arglist display
 - `type “(defmethod ”`
 - `type “(defmethod initialize-instance ”`
 - `type “(defclass foo () ((a :initarg :a) (b :initarg :b)))”,
then “(make-instance 'foo ”`

- `&ANY` is non-existing lambda-list keyword to indicate *optimize qualities* or `EVAL-WHEN` *situations*.
 - type “(declare (optimize ”
 - type “(eval-when ”
- Placing point at a variable like `*UNIVERSE*`, or constant like `+GOD+` displays its value.
 - type “*standard-output*”
- Arglist displays also works for local functions defined via `FLET`, `LABELS`.
- Likewise for local macros defined via `MACROLET`.

Completion

- Compound-Prefix Completion on TAB at the REPL, on C-c TAB in .lisp buffers.
 - type “(m-v-b<TAB>” at the REPL
 - type “(remove x seq :from<TAB>”
 - type “#\<TAB>”
 - type “(load “/hom<TAB>”
- Fuzzy Completion on C-c M-i
 - type “(mvb<C-c M-i>”
 - type “(sb:with<C-c M-i>”
 - (Use UP, DOWN to navigate, TAB to select an entry, and C-g to quit.)
- C-c C-s inserts remaining arglist onto point
 - type “(eval-when <C-c C-s>”
- C-c C-y inserts call to the defun-at-point into the REPL
 - type “(defun foo (x) <C-c C-y>” in a .lisp buffer

REPL

- Tip: Renaming identifiers
- &c

- M-n, M-p, navigating in input history
- M-r, search backwards in input history
- C-c C-c, to interrupt the inferior Lisp
- C-c M-o, to clear the REPL buffer
- Often used REPL shortcuts:
 - ,!p
switch package (also ,+p to push, and ,-p to pop)
 - ,load
load an ASDF system (includes TAB completion!)
 - ,force-load-system
recompile & load an ASDF system (e.g. to update stale .fasls!)
 - ,sayoonara
close *all* connections and kill SLIME-related buffers.
 - ,quit
close current connection only
 - ,restart
restart the inferior lisp (brave new world!)
 - ,<TAB>

Navigation

- TAB, cycle forward through inspectable parts
- S-TAB, cycle backward
- RET, follow link
- 1, go backwards
- g, reinspect

Source finding

- ., find source of object-at-point
- M- ., find source of symbol-at-point

Misc

- p, pretty-print object-at-point (useful to overcome truncating)
- M-RET, copy representation of object-at-point to the REPL (also works on the “header”, i.e. the object being inspected)

Inspector

Navigation

- `n`, next frame
- `p`, previous frame

Frame operations

- `RET` (or `t`), toggle frame details
- `v`, jump to source location of frame-at-point
- `r`, restart from frame-at-point
- `C-c C-c`, recompile location of frame-at-point

Selecting restarts

- `q`, return to toplevel
- `a`, invoke `abort` restart
- `c`, invoke `continue` restart
- `0-9`, invoke `i`th restart

Misc

- `C`, inspect the condition currently being debugged

FAQ: How can I get a local variable's value to the REPL, so I can frob it?

Answer:

- If you use the `slime-presentations` contrib (subsumed by `slime-fancy`)
 - use `Mouse-3` (right-click), then select “Copy to REPL”
 - (shortcut: `C-c C-v C-r`)
- Alternatively,
 - use `i` to inspect the value,
 - then use `M-RET` on the header representation

FAQ: How can I do single-stepping?

Answer:

- functions you want to step through, must be compiled with (debug 3)
- invoke (break), or arrange otherwise to land in the debugger
- s, to step into
- x, to step over (mnemonic: “cross”)
- o, to step out

Debugger

Use case: Recompiling frames.

- looking at a frame with too few frame details?
- recompile the frame with maximum debug settings via `C-u C-c C-c`
- now restart computation
 - either by invoking the `retry` restart possibly provided by SLIME,
 - or by restarting from an earlier frame

(It is hence a good idea to always compile an application's dispatch loop with `(debug 2)` settings such that the function becomes restartable.)

In `.lisp` buffers

- C-c C-m, macroexpand the form-at-point one single step
- C-c M-m, macroexpand the form-at-point fully (often useful on LOOP)

In the resulting `*SLIME Macroexpansion*` buffer

- g, redo last macroexpansion
- C-c C-m, still usable!
- C-c M-m, ditto
- C-_ or C-/, undo last macroexpansion operation

In .lisp buffers

- M- . , goto definition of symbol-at-point
- M- , , return from definition (works stack-like)
- C-M- . , cycle through multiple available definitions

In an XREF buffer

- RET, goto definition-at-point, do not leave XREF buffer
- SPC, goto definition-at-point, close XREF buffer
- n, next definition
- C-c C-c, recompile definition-at-point
- C-c C-k, recompile all definitions

N.B.

- When using M- . on presentations, a definition of the object-at-point (not the symbol-at-point) is searched for.

FAQ: I changed a macro. How do I recompile all functions using the macro?

Answer:

- C-c C-w C-m swank::with-bindings
- C-c C-k in the *Xref[...] buffer

NB: This is only as good as an implementation's `who-macroexpand` is.

By default, LOOP is indented oddly in Emacs:

```
(loop for x from 0 to 10
      for y from 0 to 10
      collect (cons x y))
```

Place the following snippet in your `.emacs` to fix that:

```
(setq lisp-simple-loop-indentation 1
      lisp-loop-keyword-indentation 6
      lisp-loop-forms-indentation 6)
```

So we get

```
(loop for x from 0 to 10
      for y from 0 to 10
      collect (cons x y))
```

(Alternatively, you can use the `slime-indent` contrib which is *not* subsumed by `slime-fancy`.)

In `isearch-mode`, you can use `C-w` to yank the word at point. Unfortunately, the hyphen is a word separator by default, so `C-w` works ineffectively on Lisp symbols.

But we can arrange that:

```
(defun isearch-yank-symbolic-word-or-char ()
  (interactive)
  (isearch-yank-internal
   (lambda ()
     (let ((distance (skip-syntax-forward "w_")))
       (when (zerop distance) (forward-char 1))
       (point))))))

(add-hook 'lisp-mode-hook
  (lambda ()
    (make-local-variable 'isearch-mode-map)
    (define-key isearch-mode-map "\C-w" 'isearch-yank-symbolic-word-or-char)))
```

Test case:

- place point *on front* of “*standard-input*”
- `C-s C-w`.

Put the following into `~/swank.lisp`¹

```
(in-package :swank)

(defun p (stream object &optional colon-p at-sign-p)
  (declare (ignore colon-p at-sign-p))
  (flet ((slime-stream-p (stream)
          (with-struct (connection user-output user-io trace-output repl-results)
            (default-connection)
            (member stream (list user-output user-io trace-output repl-results))))))
    (assert (slime-stream-p stream))
    (let ((id (and *record-repl-results* (save-presented-object object))))
      (finish-output stream)
      (send-to-emacs '(:presentation-start ,id))
      (send-to-emacs '(:write-string ,(prin1-to-string object)))
      (send-to-emacs '(:presentation-end ,id))
      (finish-output stream))))))
```

Test case:

- Evaluate `"(format t "The current readtable is ~/swank::p/." *readtable*)"`

¹User customization file which is executed once Swank is loaded.

The look of SLDB is highly customizable²

- search for “define-sldb-face” in `slime.el` for all available faces.
- recently introduced faces:
 - `sldb-restartable-frame-line-face`
 - `sldb-non-restartable-frame-line-face`

²The look of the inspector is also customizable, search for “`slime-inspector-.*-faces`”.

- &c

- For functions, macros, global variables, make use of XREF's who-foo!
In particular, use C-M- . + keyboard macro.
- For renaming a local binding
 - get in front of the toplevel form (C-M-a)
 - select the toplevel form (C-SPC C-M-SPC)
 - USE query-replace on the region (M-x query-replace)
